

Vaxxed teenage boys have 6-times more heart problems than unvaxxed boys have Covid

written by GEG | September 12, 2021

Dr. Tracy Beth Hoeg, MD, who is a physical medicine and rehabilitation specialist and epidemiologist at University of California-Davis, led a study that found that teenage boys are six times more likely to suffer from heart problems after receiving Covid vaccines than unvaxxed boys are likely to be hospitalized for Covid-19. Children who face the highest risk of a “cardiac adverse event” are boys aged between 12 and 15 following two doses of a vaccine. -GEG.

On June 10, we wrote about the Centers for Disease Control and Prevention (CDC) when the agency announced it was holding an ‘emergency meeting’ after **hundreds suffered rare heart inflammation** following Pfizer and Moderna COVID-19 mRNA vaccines.

On the same day, NBC News wrote a piece titled, “*Evidence grows stronger for Covid vaccine link to a heart issue, CDC says.*” The NBC story provides the missing piece from **our story**. Citing the CDC, NBC wrote:

“A higher-than-usual number of cases of a type of heart inflammation has been reported following Covid-19 vaccination, especially among young men following their second dose of an mRNA vaccine, the Centers for Disease Control and Prevention said Thursday.”

The heart condition CDC was talking about is called myocarditis, which for the most part is usually mild, but according to the CDC, a handful of patients still remain hospitalized. During a presentation to a Food and Drug Administration advisory group, Dr. Tom Shimabukuro, deputy director of the CDC’s Immunization Safety Office, said that overall, 226 cases of myocarditis or pericarditis after vaccination in people younger than age 30 have been confirmed. He said that further investigation is needed. However,

Dr. Shimabukuro also added that “We clearly have an imbalance there.”

Fast forward three months later. A major study from the University of California further confirms the CDC’s story that linked the vaccines to heart issues in teenagers.

Led by **Dr. Tracy Høeg** at the University of California, the study found that teenage boys are six times more likely to suffer from heart problems from the vaccine than to be hospitalized from Covid-19. The study also claims that healthy boys may be more likely to be admitted to the hospital with a rare side-effect of the Pfizer/BioNTech Covid vaccine that causes inflammation of the heart.

The researchers also added that children who face the highest risk of a “cardiac adverse event” are boys aged between 12 and 15 following two doses of a vaccine.
